

Data Reduction

Space Group Determination, Scaling and Intensity Statistics

Phil Evans OIST December 2011

*MRC Laboratory of Molecular Biology
Cambridge UK*

Scaling and Merging

Our job is to invert the experiment: we want to *infer* $|F|$ from our measurements of intensity I

Integration and data reduction can be done in an automated pipeline such as XIA2 (Graeme Winter): this goes from images to a list of hkl F ready for structure determination)

Automation works pretty well, but in difficult cases you may need finer control over the process

Flow scheme in CCP4

Flow scheme in CCP4

Determination of Space group

The space group symmetry is only a **hypothesis** until the structure is solved, since it is hard to distinguish between true crystallographic and approximate (non-crystallographic) symmetry.

By examining the symmetry of the diffraction pattern we can get a good idea of the likely space group

It is also useful to find the likely symmetry as early as possible, since this affects the data collection strategy

Lattice symmetry imposes constraints on the cell dimensions (eg $\alpha=\beta=\gamma=90^\circ$ for an orthorhombic lattice), but the converse is not true: cell dimensions can have special relationships accidentally. Indexing in eg Mosflm only considers lattice *geometry* not symmetry (cubic, hexagonal/trigonal, tetragonal, orthorhombic, monoclinic, or triclinic, + lattice centring P, C, I, R, or F)

The Laue group (Patterson group) is the symmetry of the diffraction pattern, so can be determined from the observed intensities. It corresponds to the space group without any translations, and with an added centre of symmetry from Friedel's law.

The space group is the point group + lattice centring + translations (eg screw dyad rather than pure dyad). Only visible in diffraction pattern as systematic absences along axes – these are not very reliable indicators as there are few axial reflections and there may be accidental absences.

Protocol for space group determination (program *POINTLESS*)

1. From the unit cell dimensions, find the highest compatible lattice symmetry (within a tolerance)
2. Score each symmetry element (rotation) belonging to lattice symmetry using all pairs of observations related by that element
3. Score combinations of symmetry elements for all possible sub-groups (Laue groups) of lattice symmetry group.
4. Score possible space groups from axial systematic absences

Scoring functions for rotational symmetry based on **correlation coefficient**, since this is relatively independent of the unknown scales.
 R_{meas} values are also calculated

systematic absences

A straightforward orthorhombic case

Scoring the symmetry operators separately sometimes allows detection of pseudo-symmetry, eg if some rotation operators are much weaker than others

Analysing rotational symmetry in lattice group P m m m

Score	Probability	Correlation coefficient	R-factor						
Nelmt	Lklhd	Z-cc	CC	N	Rmeas		Symmetry & operator (in Lattice Cell)		
1	0.948	9.54	0.95	12122	0.097		identity		
2	0.942	9.44	0.94	18346	0.121	***	2-fold l	{ 0 0 1 }	{-h,-k,+l}
3	0.949	9.58	0.96	30259	0.097	***	2-fold h	{ 1 0 0 }	{+h,-k,-l}
4	0.912	9.15	0.92	17427	0.120	***	2-fold k	{ 0 1 0 }	{-h,+k,-l}

Separate scores for each symmetry operator in maximum possible lattice symmetry

	Laue Group		Probability	Correlation coefficient	R-factor							
	ReindexOperator		Lklhd	NetZc	Zc+	Zc-	CC	CC-	Rmeas	R-	Delta	
= 1	P m m m	***	0.985	9.35	9.35	0.00	0.94	0.00	0.11	0.00	0.0	[h,k,l]
2	P 1 2/m 1		0.006	0.38	9.56	9.18	0.96	0.92	0.10	0.12	0.0	[-k,-h,-l]
3	P 1 2/m 1		0.005	-0.01	9.38	9.39	0.94	0.94	0.11	0.11	0.0	[-h,-l,-k]
4	P 1 2/m 1		0.003	-0.13	9.31	9.44	0.93	0.94	0.11	0.11	0.0	[h,k,l]
5	P -1		0.000	0.22	9.54	9.32	0.95	0.93	0.10	0.11	0.0	[h,k,l]

Combined scores for all possible Laue (point) groups down to P1

A clear indication that the Laue (Patterson) group is Pmmm (P222)

Possible axial systematic absences to determine space group

Zone	Number	PeakHeight	SD	Probability	ReflectionCondition
Zones for Laue group P m m m					
1 screw axis 2(1) [a]	3	1.000	0.296	** 0.889	h00: h=2n
2 screw axis 2(1) [b]	26	1.000	0.142	*** 0.971	0k0: k=2n
3 screw axis 2(1) [c]	46	0.997	0.097	*** 0.986	00l: l=2n

Fourier analysis of $I/\sigma(I)$

There are indications of 2_1 screw symmetry along all principle axes (though note there are only 3 observations on the a axis (h00 reflections))

Possible 2_1 axis along a

Clear 2_1 axis along b

Clear 2_1 axis along c

Possible spacegroups:

Indistinguishable space groups are grouped together on successive lines

'Reindex' is the operator to convert from the input hklin frame to the standard spacegroup frame.

'TotProb' is a total probability estimate (unnormalised)

'SysAbsProb' is an estimate of the probability of the space group based on the observed systematic absences.

'Conditions' are the reflection conditions (absences)

Spacegroup	TotProb	SysAbsProb	Reindex	Conditions
$\langle P\ 21\ 21\ 21 \rangle$ (19)	0.838	0.851		$h00: h=2n, 0k0: k=2n, 00l: l=2n$ (zones 1,2,3)
$\langle P\ 2\ 21\ 21 \rangle$ (18)	0.104	0.106		$0k0: k=2n, 00l: l=2n$ (zones 2,3)
$\langle P\ 21\ 2\ 21 \rangle$ (18)	0.025	0.026		$h00: h=2n, 00l: l=2n$ (zones 1,3)
$\langle P\ 21\ 21\ 2 \rangle$ (18)	0.012	0.012		$h00: h=2n, 0k0: k=2n$ (zones 1,2)

Best Solution space group P 21 21 21

Reindex operator: [h,k,l]
Laue group probability: 0.985
Systematic absence probability: 0.851
Total probability: 0.838
Space group confidence: 0.784
Laue group confidence 0.982

Note high confidence in Laue group, but lower confidence in space group

Unit cell: 34.16 54.8 68 90 90 90

17.00 to 1.78 - Resolution range used for Laue group search

17.00 to 1.78 - Resolution range in file, used for systematic absence check

Number of batches in file: 100

Pseudo-cubic example

Cell: 79.15 81.33 81.15 90.00 90.00 90.00 $a \approx b \approx c$

Analysing rotational symmetry in lattice group P m -3 m

[-h,l,k]	0.046	0.465	22701	0.44
[l,h,k]	0.025	0.472	22693	0.72

Alternative indexing relative to first file(s):

	Reindex operator	CC	File name
2	[h,k,l]	0.965	pk_2_001.mtz
3	[h,k,l]	0.933	pk_180_1_001.mtz
4	[h,k,l]	0.960	ip_1_001.mtz
5	[h,k,l]	0.958	rm_1_001.mtz

Because of an indexing ambiguity (pseudo-cubic orthorhombic), we must check for consistent indexing between files

Alternative indexing

If the true point group is lower symmetry than the lattice group, alternative valid but non-equivalent indexing schemes are possible, related by symmetry operators present in lattice group but not in point group (*note that these are also the cases where merohedral twinning is possible*)

eg if in space group $P3$ (or $P3_1$) there are 4 different schemes
(h,k,l) or (-h,-k,l) or (k,h,-l) or (-k,-h,-l)

For the first crystal, you can choose any scheme

For subsequent crystals, the autoindexing will randomly choose one setting, and we need to make it consistent: *POINTLESS* will do this for you by comparing the unmerged test data to a reference dataset (merged or unmerged)

Alternative indexing

If the true point group is lower symmetry than the lattice group, alternative valid but non-equivalent indexing schemes are possible, related by symmetry operators present in lattice group but not in point group (*note that these are also the cases where merohedral twinning is possible*)

eg if in space group $P3$ (or $P3_1$) there are 4 different schemes
 (h,k,l) or $(-h,-k,l)$ or $(k,h,-l)$ or $(-k,-h,-l)$

For the first crystal, you can choose any scheme

For subsequent crystals, the autoindexing will randomly choose one setting, and we need to make it consistent: *POINTLESS* will do this for you by comparing the unmerged test data to a reference dataset (merged or unmerged)

```
Space group from HKLIN file : R 3 :H
Cell:  257.89 257.89 144.72  90.00  90.00 120.00
```

Alternative index test relative to reference file

Alternative reindexing	CC	R(E ²)	Number	Cell_deviation
$[h,k,l]$	0.885	0.157	6537	0.81
$[k,h,-l]$	-0.001	0.511	6084	0.81

A confusing case in C222:

Unit cell 74.72 129.22 184.25 90 90 90

This has $b \approx \sqrt{3} a$ so can also be indexed on a hexagonal lattice,
lattice point group P622 (P6/mmm), with the reindex operator: $h/2+k/2, h/2-k/2, -l$

Conversely, a hexagonal lattice may be indexed as C222 in three distinct ways, so there is a 2 in 3 chance of the indexing program choosing the wrong one

Score each symmetry operator in P622

Only the orthorhombic symmetry operators are present

Scaling and Data Quality

Choices

- What scaling model?
 - the scaling model should reflect the experiment
 - considerations of scaling may affect **design** of experiment*
- Is the dataset any good?
 - should it be thrown away immediately?
 - what is the real resolution?
 - are there bits which should be discarded (bad images)?

Why are reflections on different scales?

Various physical factors lead to observed intensities being on different scales. Some corrections are known eg Lorentz and polarisation corrections, but others can only be determined from the data

Scaling models should if possible parameterise the experiment so different experiments may require different models

Understanding the effect of these factors allows a sensible design of correction and an understanding of what can go wrong

- (a) Factors related to incident beam and the camera
- (b) Factors related to the crystal and the diffracted beam
- (c) Factors related to the detector

Factors related to incident Xray beam

- (a) incident beam intensity: variable on synchrotrons and not normally measured. Assumed to be constant during a single image, or at least varying smoothly and slowly (relative to exposure time). If this is not true, the data will be poor
- (b) illuminated volume: changes with φ if beam smaller than crystal
- (c) absorption in primary beam by crystal: indistinguishable from (b)
- (d) variations in rotation speed and shutter synchronisation. These errors are disastrous, difficult to detect, and (almost) impossible to correct for: we **assume** that the crystal rotation rate is constant and that adjacent images exactly abut in φ . (*Shutter synchronisation errors lead to partial bias which may be **positive**, unlike the usual negative bias*)

Data collection with open shutter (eg with Pilatus detector) avoids synchronisation errors (though variation in rotation speed could still cause trouble, and there is a dead time during readout)

Factors related to crystal and diffracted beam

(e) Absorption in secondary beam - serious at long wavelength (including $\text{CuK}\alpha$)

(f) radiation damage - serious on high brilliance sources. Not easily correctable unless small as the structure is changing

Maybe extrapolate back to zero time? (but this needs high multiplicity)

The relative B-factor is largely a correction for the average radiation damage

Factors related to the detector

- The detector should be properly calibrated for spatial distortion and sensitivity of response, and should be stable. Problems with this are difficult to detect from diffraction data. There are known problems in the tile corners of CCD detectors (corrected for in XDS)
- The useful area of the detector should be calibrated or told to the integration program
 - Calibration should flag defective pixels (hot or cold) and dead regions eg between tiles
 - The user should tell the integration program about shadows from the beamstop, beamstop support or cryocooler (define bad areas by circles, rectangles, arcs etc)

Scaling

Scaling tries to make symmetry-related and duplicate measurements of a reflection equal, by modelling the diffraction experiment, principally as a function of the incident and diffracted beam directions in the crystal. This makes the data **internally consistent**.

Note that we do not know the true intensities and an internally-consistent dataset is not necessarily correct. Systematic errors which are the same for symmetry-related reflections will remain

$$\text{Minimize } \Phi = \sum_{hl} w_{hl} (I_{hl} - 1/k_{hl} \langle I_h \rangle)^2$$

I_{hl} l 'th intensity observation of reflection h

k_{hl} scale factor for I_{hl}

$\langle I_h \rangle$ current estimate of I_h

$g_{hl} = 1/k_{hl}$ is a function of the parameters of the scaling model

$g_{hl} = g(\varphi \text{ rotation/image number}) \cdot g(\text{time}) \cdot g(s) \quad \dots \text{other factors}$
Primary beam s_0 B-factor Absorption

Scaling

After scaling, the remaining differences between observations can be analysed to give an *indication* of data quality, though not necessarily of its absolute correctness.

Measures of internal consistency:

R-factors & correlation coefficients:

$$R_{\text{merge}} (R_{\text{sym}}) = \sum | I_{\text{hl}} - \langle I_{\text{h}} \rangle | / \sum | \langle I_{\text{h}} \rangle |$$

traditional overall measures of quality, but increases with multiplicity
although the data improves

$$R_{\text{meas}} = R_{\text{r.i.m.}} = \sum \sqrt{(n/n-1)} | I_{\text{hl}} - \langle I_{\text{h}} \rangle | / \sum | \langle I_{\text{h}} \rangle |$$

multiplicity-weighted, better (but larger)

$$R_{\text{p.i.m.}} = \sum \sqrt{(1/n-1)} | I_{\text{hl}} - \langle I_{\text{h}} \rangle | / \sum | \langle I_{\text{h}} \rangle |$$

“Precision-indicating R-factor” gets better (smaller) with increasing
multiplicity, ie it estimates the precision of the merged $\langle I \rangle$

CC pairwise correlation coefficients (see later)

Running SCALA from ccp4i interface

Click if you have anomalous scattering
(changes the statistics and the outlier rejection)

The screenshot shows the CCP4i interface with the 'Data Reduction' menu open. The 'Scale and Merge Intensities' option is highlighted. The main window displays the SCALA configuration for 'Gamma ear Xe'. The 'Separate anomalous pairs for merging statistics' checkbox is checked. The 'MTZ in' field is set to 'gamma_xe1.mtz'. The 'MTZ out' field is set to 'gamma_xe1_scala1.mtz'. The 'Scaling Protocol' section shows 'Scale' set to 'on rotation axis with secondary beam correction' and 'Bfactor scaling' set to 'isotropic'. The 'Define scale ranges along rotation axis by' field is set to 'rotation interval' with a value of 5. The 'Secondary beam correction maximum number of spherical harmonics' is set to 6. The 'Independent Bfactors defined by' field is set to 'rotation interval' with a value of 20. The 'Apply tails correction' checkbox is unchecked. The 'Run' button is visible at the bottom.

Usually use the default scaling options

Running SCALA from ccp4i interface

The image shows the CCP4i interface for running SCALA. The 'Data Reduction' menu is open, and 'Scale and Merge Intensities' is selected. The 'Scala - Scale Experimental Intensities' dialog box is displayed, showing the following options:

- Job title: Gamma ear Xe
- ☐ Customise Scala process (default is to refine & apply scaling)
- ☒ Separate anomalous pairs for merging statistics
- ☒ Run **Ctruncate** to output Wilson plot and SFs after scaling ☒ and output a single MTZ file
- ☒ Ensure unique data & add FreeR column for 0.05 fraction of data.
- ☐ Generate Patterson map and do peaksearch to check for pseudo-translations
- MTZ in: Examples **gamma_xe1.mtz** [Browse] [View]
- ☐ Override automatic definition of 'runs' to mark discontinuities in data
- ☐ Exclude data resolution less than 17.000 Angstrom or greater than 1.780 Angstrom
- MTZ out: Examples **gamma_xe1_scala1.mtz** [Browse] [View]
- ☐ Convert to SFs & Wilson Plot
- Use **dataset name** as identifier to append to column labels
- ☒ Copy FreeR from another MTZ
- ☐ Extend reflector
- ☐ Bfactor scaling
- ☐ Observations Used & Handling of Partial

Two light blue text boxes provide instructions:

- Use this option for your first dataset ...
- ... or this one for subsequent ones

Running AIMLESS from ccp4i interface

The screenshot shows the CCP4i interface with the 'Data Reduction' panel on the left and the main configuration window on the right. The 'Symmetry, Scale, Merge (Aimless)' option is selected in the left panel. The main window has several sections: 'Job title' (Gamma ear Xe), 'Custom scaling options' (with 'Separate anomalous pairs for outlier rejection & merging statistics' checked), 'Input reflection file type' (MTZ file), 'Project name' (Gamma), 'crystal name' (Gamma), 'dataset name' (xe1a), 'HKLIN #1' (Full path.. /Users/PhilStuff/Projects/Gamma/Xe/GearXe1a_sort.mtz), 'HKLOUT' (MtzUnmrg, GearXe1a_scaled1.mtz), 'Resolution and batch exclusions' (Exclude data resolution less than 16.116 Angstrom or greater than 1.788 Angstrom), 'Scaling Protocol' (Scale with automatic default settings), and 'Define Runs' (Accepted and Excluded Data, Reject Outliers, SD Correction Protocols, Observations Used & Handling of Partial, Scaling Details, Truncate: convert to structure amplitudes and final output). The 'Run' button is at the bottom.

Options for Pointless

Click if you have anomalous scattering (changes the statistics and the outlier rejection)

Input file(s)

Usually use the default scaling options

Along axis a*

from half-dataset correlation coefficient > 0.50: limit = 1.79A == maximum resolution

from Mn(I/sd) > 2.00: limit = 1.84A

Along axis b*

from half-dataset correlation coefficient > 0.50: limit = 1.79A == maximum resolution

from Mn(I/sd) > 2.00: limit = 1.79A == maximum resolution

Along axis c*

from half-dataset correlation coefficient > 0.50: limit = 1.79A == maximum resolution

from Mn(I/sd) > 2.00: limit = 1.79A == maximum resolution

Average unit cell: 34.16 54.82 68.05 90 90 90

Space group: P 21 21 21

Average mosaicity: 0.90

Minimum and maximum SD correction factors: Fulls 0.19 3.79 Partial 2.87 24.07

Graphs: Analyses against “batch” (image number or “time”)

- check for level of radiation damage
 - if you cut back from the end, there is a trade-off between damage and completeness
- check for bad images or regions

A good case

No great difference between average scale Mn(k) & scale at $\theta=0$

Small variation in relative B-factor

Uniform and low R_{merge}

A bad case: two crystals, both dying, both incomplete

Acceptable limit depends on resolution: $B < -10$ is *bad*!

Increasing difference between average scale $Mn(k)$ & scale at $\theta=0$

relative B gets more negative with radiation damage

High and increasing R_{merge}

“Resolution limit” where I/σ falls below 1.0 getting worse

The relative B-factor gives a resolution-dependent scale factor as a function of “time” (dose): average radiation damage decay is greater at high resolution

$$k(\text{time}) = \exp[-2B(\text{time}) \sin^2\theta/\lambda^2]$$

Graph of R_{merge} vs batch may also detect individual bad images, or bad regions, that should be investigated or rejected

One bad (weak) image

Bad region where integration had gone wrong

Graph of R_{merge} vs batch may also detect individual bad images, or bad regions, that should be investigated or rejected

Omitting bad image

Reprocessed

Analyses against intensity

R_{merge} vs. I not generally useful (since R is a fractional measure, it will always be large for small I), but the value in the top intensity bin should be small

Improved estimate of $\sigma(I)$

The error estimate $\sigma(I)$ from the integration program is too small particularly for large intensities. A “corrected” value may be estimated by increasing it for large intensities such that the mean scatter of scaled observations on average equals $\sigma'(I)$, in all intensity ranges

$$\text{Corrected } \sigma'(I)^2 = \text{SDfac}^2 [\sigma^2 + \text{SdB} \langle I_h \rangle + (\text{SdAdd} \langle I_h \rangle)^2]$$

SDfac, **SdB** and **SdAdd** are adjustable parameters

Analyses against resolution

What is the real resolution? not an easy question to answer

May depend on what you want the data for: more stringent for experimental phasing than for refinement

Anisotropic data needs a less stringent overall cut-off to keep best data

Collect and integrate a little beyond visible spots, then cut back in the merging step

R_{merge} is not particularly useful: it gets higher at high resolution

$\langle I/\sigma(I) \rangle$ after merging (blue line) should be $> \sim 1-2$

CC between random half-datasets should be $> \sim 0.5$

Anisotropy analysis

Maximum resolution limits along a^* , b^* , c^* (in cones along axes)
from half-dataset CC or $Mn(I/\sigma)$

Default criteria:

$CC > 0.5$

$Mn(I/\sigma) > 2.0$

half-dataset CC

$Mn(I/\sigma)$

Estimates of resolution limits: overall
from half-dataset correlation coefficient > 0.50 : limit = 3.11Å
from $Mn(I/sd) > 2.00$: limit = 3.30Å

Estimates of resolution limits along reciprocal lattice axes:

Along axis a^*

from half-dataset correlation coefficient > 0.50 : limit = 3.62Å

from $Mn(I/sd) > 2.00$: limit = 3.76Å

Along axis c^*

from half-dataset correlation coefficient > 0.50 : limit = 2.90Å == maximum resolution

from $Mn(I/sd) > 2.00$: limit = 2.90Å == maximum resolution

Note: in this tetragonal case there are only 2 independent directions

Completeness

Data completeness is important, preferably in all resolution shells, though you can probably get away with some incompleteness at the outer edge.

See James Holton's movies for an illustration of the importance of completeness <http://ucxray.berkeley.edu/~jamesh/movies/>

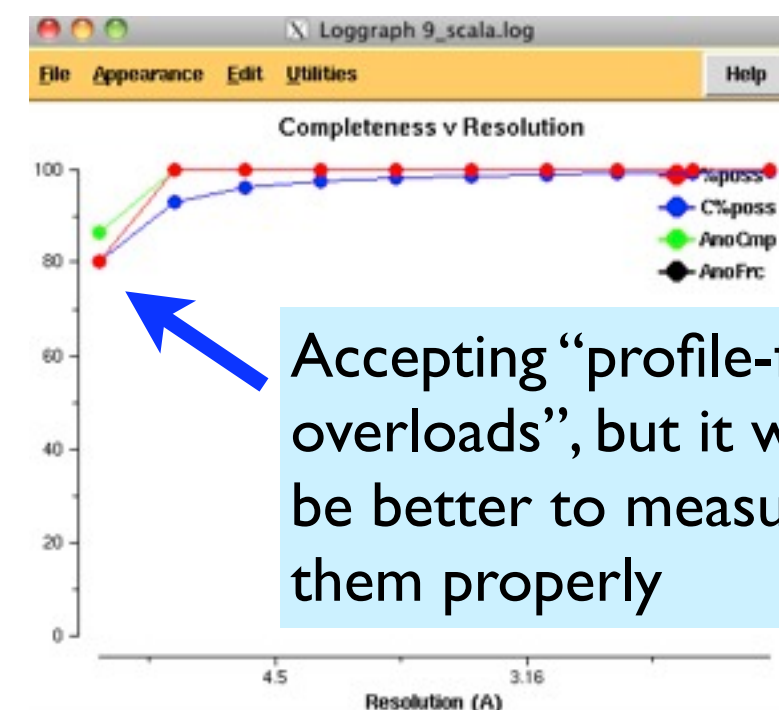

Don't lose the strong low resolution reflections as overloads

Completeness

Data completeness is important, preferably in all resolution shells, though you can probably get away with some incompleteness at the outer edge.

Outliers

Detection of outliers is easiest if the multiplicity is high

Removal of spots behind the backstop shadow does not work well at present: usually it rejects all the good ones, so tell Mosflm where the backstop shadow is.

Reasons for outliers

- outside reliable area of detector (eg behind shadow)

specify backstop shadow, calibrate detector

- ice spots

do not get ice on your crystal!

- multiple lattices

find single crystal

- zingers

- bad prediction (spot not there)

improve prediction

- spot overlap

lower mosaicity, smaller slice, move detector back

deconvolute overlaps

*Rejects lie on

Position of rejects on detector

Detecting anomalous signals

The data contains both I^+ (hkl) and I^- (-h-k-l) observations and we can detect whether there is a significant difference between them.

Split one dataset randomly into two halves, calculate correlation between the two halves or compare different wavelengths (MAD)

Plot ΔI_1 against ΔI_2 should be elongated along diagonal

Strong
anomalous signal

Ratio of width of distribution along diagonal to width across diagonal

Slope > 1.0 means that $\Delta I > \sigma$

“RMS correlation ratio”

Detecting anomalous signals

The data contains both I^+ (hkl) and I^- (-h-k-l) observations and we can detect whether there is a significant difference between them.

Split one dataset randomly into two halves, calculate correlation between the two halves or compare different wavelengths (MAD)

Plot ΔI_1 against ΔI_2 should be elongated along diagonal

Weak but useful anomalous signal

Ratio of width of distribution along diagonal to width across diagonal

“RMS correlation ratio”

Estimation of amplitude $|F|$ from intensity I

If we knew the true intensity J then we could just take the square root

$$|F| = \sqrt{J}$$

But measured intensities I have an error $\sigma(I)$ so a small intensity may be measured as negative.

The “best” estimate of $|F|$ larger than $\sqrt{I}$ for small intensities ($< \sim 3 \sigma(I)$) to allow for the fact that we know that $|F|$ must be positive

[c]truncate estimates $|F|$ from I and $\sigma(I)$ using the average intensity in the same resolution range: this give the prior probability $p(J)$

$$E(F ; I, \sigma(I)) = \int_0^{\infty} F p(I ; J, \sigma(I)) p(J) dJ$$

French & Wilson 1978

Intensity statistics

We need to look at the distribution of intensities to detect twinning

Assuming atoms are randomly placed in the unit cell, then

$$\langle I \rangle(s) = \langle F F^* \rangle(s) = \sum_j g(j, s)^2$$

where $g(j, s)$ is the scattering from atom j at $s = \sin\theta/\lambda$

Average intensity falls off with resolution, mainly because of atomic motions (B-factors)

$$\langle I \rangle(s) = C \exp(-2 B s^2)$$

Wilson plot: $\log(\langle I \rangle(s))$ vs s^2

This would be a straight line if all the atoms had the same B-factor

For the purposes of looking for crystal pathologies, we are not interested in the variation with resolution, so we can use “normalised” intensities which are independent of resolution

Normalised intensities: relative to average intensity at that resolution

$$Z(h) = I(h)/\langle I(s) \rangle \approx |E|^2$$

$$\langle Z(s) \rangle = 1.0 \text{ by definition}$$

$$\langle Z^2(s) \rangle > 1.0 \text{ depending on the distribution}$$

$\langle Z^2(s) \rangle$ is larger if the distribution of intensities is wider: it is the 2nd moment ie the *variance* (this is the 4th moment of E)

many weak reflections

few weak reflections

Cumulative distribution of Z : $p(Z)$ vs. Z

many weak reflections

few weak reflections

$p(Z_I)$ is the proportion of reflections with $Z < Z_I$

Summary

Questions & Decisions

- What is the point group (Laue group)?
- What is the space group?
- Is there radiation damage: should data be cut away from the end (possibly at the expense of resolution)?
- What is the best resolution cut-off?
- Is there anomalous signal (if you expect one)?
- Are the data twinned?
- Is this dataset better or worse than ones you have already?

Other features of the intensity distribution which may obscure or mimic twinning

Translational non-crystallographic symmetry:

whole classes of reflections may be weak

eg h odd with a NCS translation of $\sim 1/2, 0, 0$

$\langle I \rangle$ over all reflections is misleading, so Z values are inappropriate

The reflection classes should be separated (not yet done)

Anisotropy: $\langle I \rangle$ is misleading so Z values are wrong

ctruncate applies an anisotropic scaling before analysis

Overlapping spots: a strong reflection can inflate the value of a weak neighbour, leading to too few weak reflections

this mimics the effect of twinning
